

Presentation Overview

1. What is the project?
2. How Organization Admins and Recruiters use it
3. What is completed and what comes next

1. What is the project?

The AI Recruitment Platform is a centralized recruitment application designed to help an organization manage its complete hiring workflow in one place — from creating a job to receiving applications, storing resumes, reviewing candidates, and progressing applications through recruitment stages.

Core purpose

- **One workspace for hiring:** Organization Admins and Recruiters can manage jobs, candidates and applications without dealing with technical infrastructure.
- **Real candidate flow:** A recruiter creates a job → publishes it → a candidate applies through the public job page → uploads a resume → the application is stored → the recruiter reviews and manages it.
- **Future-ready architecture:** The local demo is being built so AI Screening, Assessments, Campus Drives, Notes and Reports can be added as working recruitment capabilities.

Main user experience

Organization Admin	Recruiter
Manages organization-level recruitment operations, users/team access and available hiring data.	Creates and manages jobs, reviews candidates/applications, opens candidate details and updates application progress.
Works through a business-oriented portal without exposing backend concepts such as RLS, tenant IDs or database internals.	Works through a focused recruitment UI designed for daily hiring activities.

Platform-level administration is intentionally separate: technical/platform information can be visible to the Platform Super Admin where appropriate, but it is not part of the normal recruiter or organization workflow.

2. How will it work?

The demonstration should be presented as a realistic hiring journey rather than as a collection of disconnected screens.

A. Organization Admin workflow

- **Login** → enters the organization portal.
- **Manage team** → manages organization users/recruiters according to available permissions.
- **Manage hiring operations** → oversees jobs, candidates and applications.
- **Review activity** → uses recruitment information and reports to understand hiring progress.

B. Recruiter workflow — the main demonstration

#	Action	What happens
1	Login	Recruiter signs in and reaches the recruiter dashboard.
2	Create Job	Adds job title, description and relevant job information.
3	Publish Job	Makes the job available on the public/applicant-facing career page.
4	Candidate Applies	Candidate opens the public job, enters details and submits an application.
5	Resume Upload	Candidate uploads a resume; the backend validates and stores the file locally.
6	Application Stored	Candidate, resume and application are associated with the correct job and organization.
7	Recruiter Review	Recruiter views candidates, applications, candidate details and resume.
8	Manage Status	Recruiter progresses the application through supported statuses.
9	Communication	Relevant email notifications can be connected through Resend when credentials/configuration are available.

Demo story: Job creation → Public job → Candidate application → Resume upload → Stored candidate/application → Recruiter review → Application status update.

The interface should remain responsive across desktop, tablet and mobile, with Dark/Light mode available.

3. What is done and what needs to be done?

Current local implementation status is based on the latest development audit and test report.

Completed / working in the local demo

- Authentication and role-based access flow for the existing test accounts.
- Responsive improvements including mobile navigation/drawer and contained data tables.
- Dark/Light theme system with persistence.
- Normal recruiter UI cleaned up so technical tenancy/infrastructure details are not exposed.
- Public organization/job browsing and applicant-facing application flow.
- Job creation and job lifecycle actions such as publish/hold/close.
- Candidate application with real resume file upload.
- Local resume storage abstraction and backend validation.
- PostgreSQL persistence for candidates/applications and association with the relevant job/organization.
- Recruiter candidate detail and resume access with permission/tenant isolation checks.
- Search/filter support across Jobs/Candidates/Applications.
- Reports dashboard using live database queries rather than hardcoded numbers.
- Backend regression suite reported clean: 69/69 tests passing; frontend typecheck/tests clean at the latest audit point.

Next implementation priorities

- **AI Screening (Phases 5–6):** connect a real AI provider, define screening inputs/outputs and add explainable screening results.
- **Assessments (Phase 7):** create assessment workflows, candidate assignment, submission and recruiter review.
- **Campus Drives (Phase 8):** support campus hiring events, candidates, applications and drive-specific management.
- **Notes / recruitment workflow (Phase 9):** add recruiter notes and supporting workflow capabilities.
- **Reports (Phase 10):** expand reporting beyond the current live dashboard into useful recruitment metrics and views.
- **Email / Resend:** configure real credentials and wire appropriate candidate/recruiter notifications rather than using fake production behavior.

Definition of success for the local demo

A recruiter can demonstrate a complete realistic recruitment cycle locally: **create a job → publish it → candidate applies → resume is uploaded and stored → recruiter finds the candidate → opens the application/resume → updates the application status**. Once the local workflow is stable and accepted, the platform can move toward production deployment and deeper AI/recruitment capabilities.
